

Using Human Laboratory Methods to Understand the Pharmacokinetics and Pharmacodynamics of Oral Cannabinoid Products

Tory Spindle, PhD.
Johns Hopkins University School of Medicine
Behavioral Pharmacology Research Unit

Presented at ASAM State of the Art Course 2022

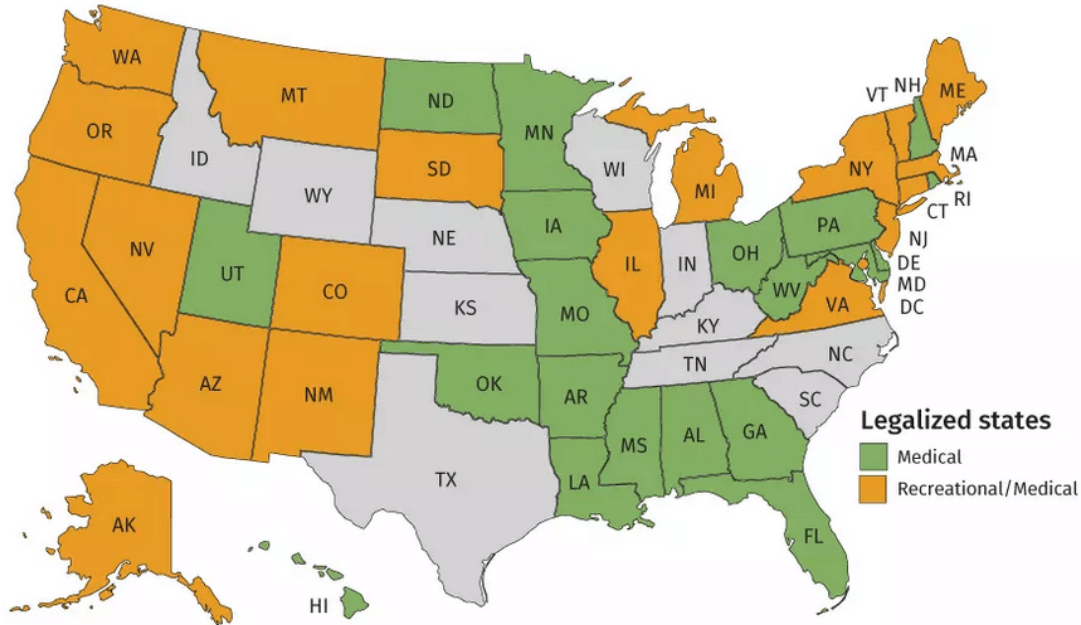

Disclosure Information

Tory Spindle, PhD.

- Dr. Spindle has served as a consultant to Canopy Growth Inc
- The research being presented today is not related to this consulting work

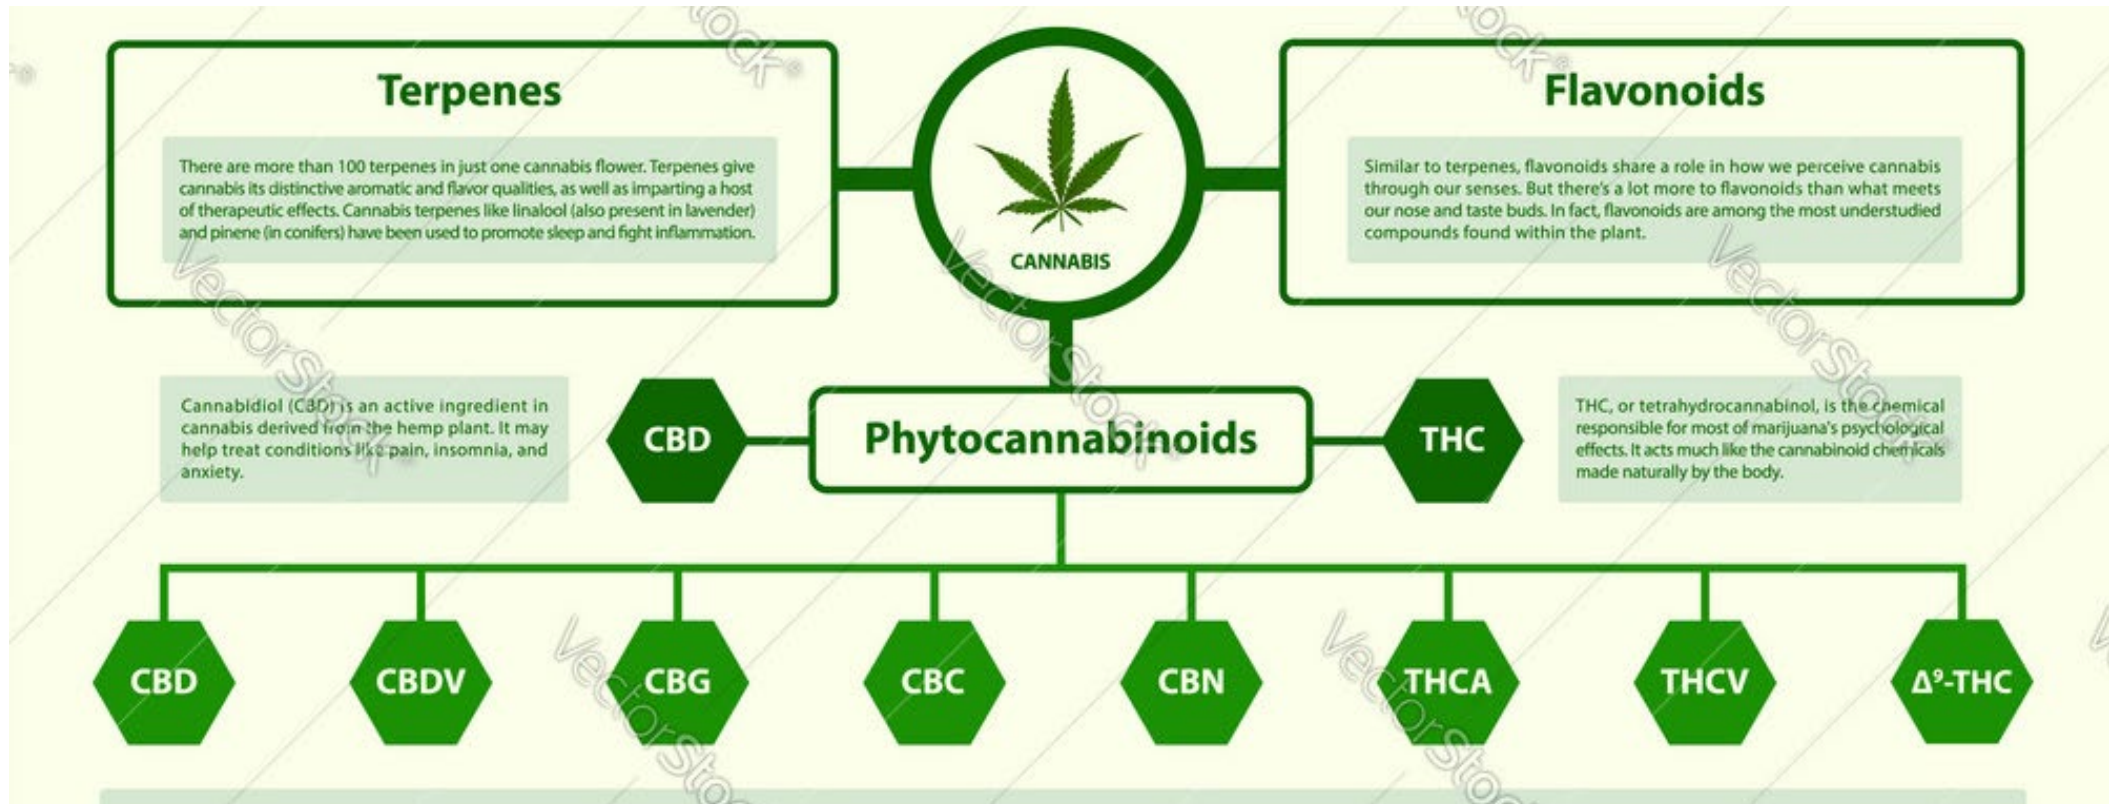

Cannabis Laws are Changing

Note: Does not include states that have legalized only CBD-based oils.
© 2022 MJBiz, a division of Emerald X, LLC

- 38 U.S. states + Washington D.C. allow medicinal and 19 states (+ D.C.) allow non-medical “recreational” cannabis use
- Cannabis is still considered illegal at the federal level
- Cannabis with $\leq 0.3\%$ THC (*aka* Hemp) and anything derived from it EXCEPT THC is legal

Cannabis Contains Many Compounds

Many Forms of Cannabis + Routes of Administration

Many Different Oral Cannabis Products or “Edibles”

Various food matrices and liquid vehicles for edibles.

Background on Cannabis Edibles

- Edibles are now the second most popular form of cannabis (next to smoked flower)
- Approximately 1/3rd of cannabis users have tried edibles
- Users report that the duration and intensity of edibles' effects are highly unpredictable (possibly due to product diversity, inaccurate labeling, difficulty with dose titration)
- Responsible for the majority of ER visits related to over-intoxication from cannabis

Questions About Cannabis Edibles

- How do cannabis edible effects differ from smoking or vaping cannabis? Are the effects weaker/stronger at a given THC dose? Does the time-course of effects differ?
- What product features or user factors may influence the acute effects of edibles?
- Do edibles have drug-drug interactions with other medications?
- Do edibles impair driving performance? Can impairment be detected in individuals who recently used them?

Systematic Studies Needed

- Clinical Laboratory Research
- Johns Hopkins University Behavioral Pharmacology Research Unit (BPRU)

Clinical Laboratory Methods

Biological samples

- Measure THC + metabolites and other cannabinoids in blood, oral fluid, and urine

Subjective effects

- Positive effects (abuse liability)
- Negative effects (adverse events)

Cognitive performance testing

- Working memory
- Psychomotor functioning
- Divided Attention

Vital Signs (Heart rate, blood pressure)

Answer Subjective Questions

Perform Cognitive Tasks

Record Vital Signs

Inpatient Stay

Clinical Laboratory Methods (cont.)

Simulated Driving Performance

Overview

- PK/PD differences between edibles and other routes of administration (smoking, vaping)
- Interactive effects of THC + CBD
- Drug-drug interactions between edibles and common prescription or OTC medications
- Influence of product formulation and diet
- Measuring impairment from cannabis edibles

Route of Administration Studies – Smoked vs. Vaporized vs. Oral Cannabis

- Controlled cannabis dosing studies
 - Oral cannabis dosing studies – cannabis-infused brownies (0, 10, 25, 50 mg THC)
 - Smoked and vaporized study (0, 10, 25 mg THC)
- Subjective, cognitive, cardiovascular, and pharmacokinetic (i.e., urine, blood, oral fluid) assessments in each
- Similar protocol – assessments timepoints mirrored across studies
- Each focused on infrequent cannabis users who had no recent cannabis exposure

Subjective Ratings of “Feel Drug Effect”

THC + CBD Interactions in Edibles

- Two most common cannabinoids in edibles are THC and CBD
- Entourage Effect Theory (Russo, 2011)
- Often alleged that CBD can mitigate THC's negative effects. Evidence is mixed
- Implications for medical use of cannabinoids
 - Narrow therapeutic window of dronabinol

THC/CBD Drug-Drug Interactions

- Medical cannabis/CBD users often use other prescription medications
- THC and CBD are metabolized by cytochrome P450 enzymes, which are also the primary metabolic pathway of many medications. Potential for drug-drug interactions
- Few controlled clinical studies have characterized drug-drug interactions between THC/CBD and other medications

Study Design Overview

- Double blind, placebo controlled, randomized, crossover study
- Healthy adults completed 3 outpatient drug administration sessions:
 - Placebo Brownie
 - 20mg THC Brownie – high THC extract
 - 20mg THC + 640mg CBD Brownie – high CBD extract
- 30-min after consumption of the cannabis brownie, participants consumed a drug cocktail (the Inje cocktail) to probe 5 different CYP enzymes

Study Design Overview (cont.)

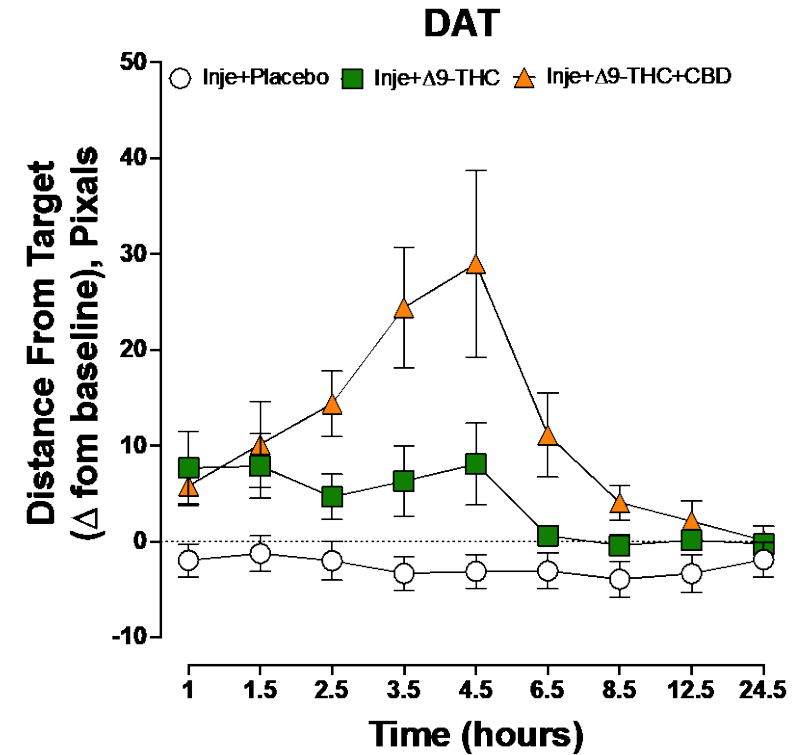

*all therapeutic or sub- therapeutic doses

Caffeine	Stimulant present in coffee	100mg	CYP1A2
Losartan	Brand name: Cozaar; for hypertension	25mg	CYP2C9
Omeprazole	Brand name: Prilosec OTC; For heartburn and indigestion	20mg	CYP2C19
Dextromethorphan	Cough suppressant; in numerous cough medications	30mg	CYP2D6
Midazolam	Benzodiazepine; used most often for anesthesia	2mg	CYP3A

CYP3A

CYP1A2

CPY2C9

5-OH Omeprazole

Dextroprhan

1-OH Midazolam

Paraxanthine

Losartan Carboxylic Acid

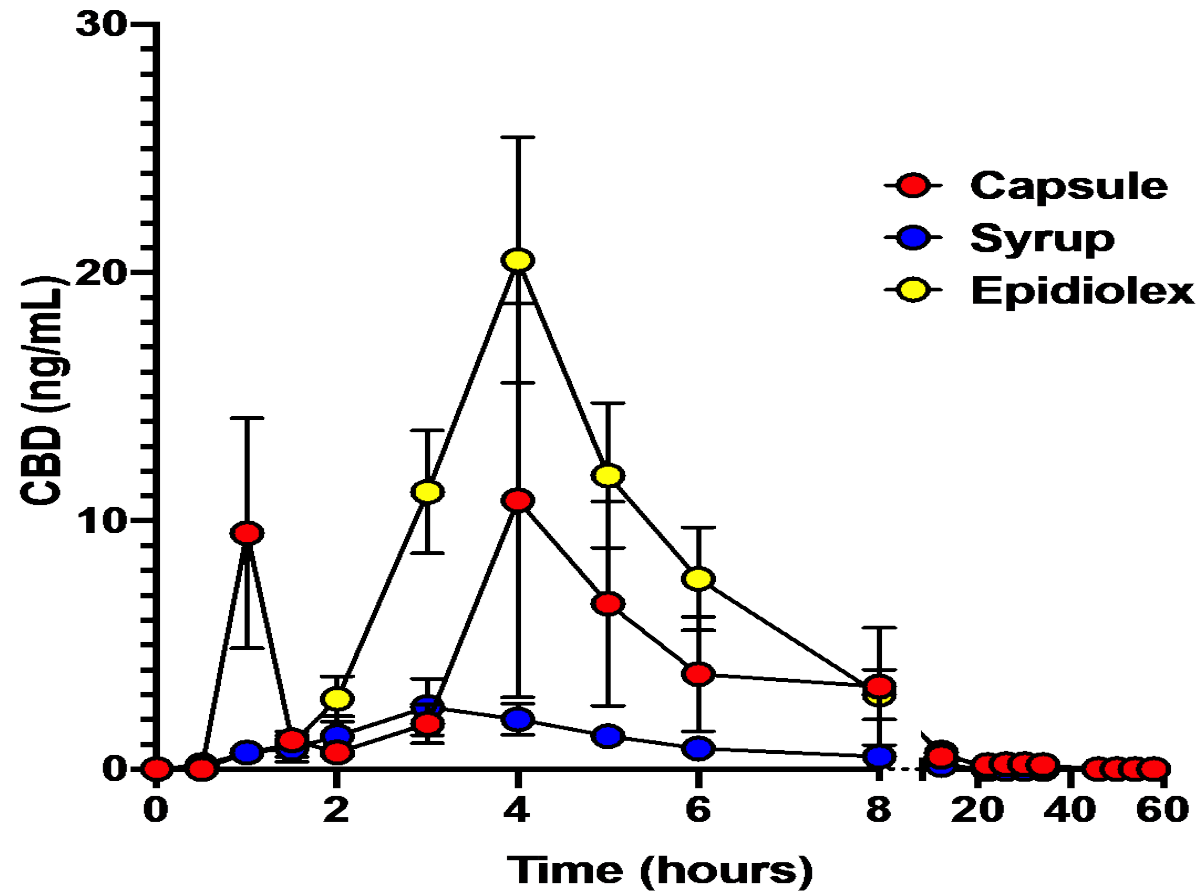

Many Different Oral Formulations

- The liquid vehicle or food matrix of oral products could impact bioavailability
- Three different oral solutions were administered in recent study – all contained 100mg CBD
- Capsule (N=6)
- Epidiolex (N=6)
- Syrup (used for commercial cough medications) (N=6)

Blood CBD Concentrations by Oral Formulation

Dietary Factors

Ingesting CBD after fasting vs. with a low-fat meal.

Blood CBD following CBD Syrup: Fasted vs. Non-Fasted

Measuring Cannabis Impairment

- With expanding legalization, the incidence of driving under the influence of cannabis (DUIC) is increasing
- Increasing need to be able to objectively detect cannabis impairment at the roadside and elsewhere
- Currently, the primary methods used to detect cannabis impairment at the roadside are:
 - Blood THC levels (i.e., per se limits or zero-tolerance thresholds)
 - Effects-based laws (i.e., field sobriety tests)
 - Are these effective for edibles?

Is Blood THC Related to Impairment?: Oral Cannabis

Next Steps: Simulated Driving Impairment Research

- Next Steps – new project that is examining interactive effects between cannabis edibles and alcohol on simulated driving performance
- Study 1: Oral cannabis + alcohol; Study 2: Vaporized cannabis + alcohol:
 - Placebo cannabis + Placebo alcohol
 - Low dose cannabis (10mg THC) + Placebo alcohol
 - High dose cannabis (25mg THC) + Placebo alcohol
 - Placebo cannabis + Alcohol (0.05% BAC)
 - Low dose cannabis (10mg THC) + Alcohol (0.05% BAC)
 - High dose cannabis (25mg THC) + Alcohol (0.05% BAC)
 - Placebo cannabis + Alcohol (0.08% BAC)

Overall Summary

- Cannabis edible effects are delayed, but of a similar magnitude to other routes of administration (e.g., smoked) at a given THC dose (important implications for dose titration and adverse events)
- CBD appears to exacerbate effects of THC, likely due to PK interactions when both are administered orally
- Oral THC/CBD have profound drug-drug interactions with other medications
- Product formulation and user diet greatly impacts cannabinoid absorption
- Novel approaches to measuring cannabis impairment are needed to detect cannabis-impaired drivers
